

MEASURING AND MONITORING ORGANICS IN DRINKING WATER

Drinking water comes from many different sources such as rivers, lakes, aquifers, and man-made reservoirs. Treatment processes for source water varies widely depending on the source itself, as well as the impurities of the source water. One of the most prevalent impurities in source water is organic material. Organics in source water come from naturally occurring organic matter (NOM) as well as introduced organics coming from pollution. Organic material in drinking water affects the color, taste, and odor of water. In addition, during the disinfection process residual chlorine can react with the organics to form disinfection byproducts (DBPs) that are potentially carcinogens, such as trihalomethanes (THMs) and haloacetic acids.

To avoid the formation of DBPs, it is important to monitor and measure NOM. The **monitoring** of NOM in raw water is also a first indication for unexpected events and helps to calculate the capacity of a treatment process. A well-established method for monitoring organic load is to measure UV absorption at 254 nm, as many organics absorb UV light at that wavelength. The amount of absorbed UV light is used to monitor NOM levels.

The common parameter for the **direct measurement** of NOM is total organic carbon (TOC), which can be measured online and in the lab. While UV absorption detects only dissolved and double bonded carbon, TOC provides a quantified analysis of the total organic load in your water.

Hach® provides solutions for event monitoring and qualified TOC analyses both online and in the lab:
