Nitric Oxide in Tumour Biology and Cancer Therapy. Part 1: Physiological Aspects

G. M. Tozer and S. A. Everett

Gray Laboratory Cancer Research Trust, Mount Vernon Hospital, Northwood, UK

INTRODUCTION

In the early 1980s, the discovery that nitric oxide (NO) could be released from stimulated endothelial cells, resulting in blood vessel dilation, represented the discovery of a completely new type of messenger molecule. Uniquely, the physiological effects of NO could be attributed to its small size, diffusibility and chemical reactivity. Roles for NO as a secondary messenger molecule, a neurotransmitter and, at higher concentrations, a cytotoxin, have been found in the disparate fields of cardiovascular physiology, neurobiology and immunology [1-11].

Evidence is now accumulating that NO-producing pathways are upregulated in many tumours, suggesting a biological role for NO which could be targeted for therapeutic purposes [12]. The growth of solid tumours is regulated by the interactions between cells of the tumour vasculature (such as endothelial cells and vascular smooth muscle cells), tumour infiltrating immune cells (such as macrophages), and the tumour cells themselves. Endogenous NO production has been demonstrated in all these cell types.

The purpose of this and the accompanying paper [13] is to review the current knowledge of the biology of NO that is most relevant to tumours and to indicate areas in which modification of NO pathways could be exploited in cancer therapy. In this paper, the biochemical pathways associated with NO production are briefly outlined, followed by the evidence for upregulation of NO-producing pathways in tumours and the possible role of tumour hypoxia in the patterns observed. The major roles of NO in normal tissues and evidence for a protective role in tumours are described.

NITRIC OXIDE SYNTHASES

NO is produced by the action of the enzyme nitric oxide synthase (NOS) [14,15]. NOS catalyses the NADPH and O₂-dependent oxidation of L-arginine to citrulline and NO, with N⁵-hydroxy-L-arginine

(NHA) as an enzyme-bound intermediate (Fig. 1) [16]. NOS occurs in at least three distinct isoforms [17]. There are two major constitutive, Ca²⁺-regulated isoforms (eNOS or hNOS), initially identified in neuronal tissue (nNOS or hNOS) and endothelial cells (eNOS or hNOSII). A third, inducible and Ca²⁺-independent, isoform (iNOS or hNOSII) was discovered in macrophages and is under transcriptional control from endotoxin and various cytokines such as tumour necrosis factor- α (TNF- α), interferins (e.g. IFN- γ) and interferon- γ . Mechanistic studies indicate that catalysis by all isoforms involves two successive monooxygenase reactions [5,14,18], the first a ferri-haem dependent hydroxylation of a guanidino nitrogen of L-arginine, yielding NHA, and the second a nucleophilic attack by proto-haem on the guanidino carbon of NHA or on the free radical oxygenation product of NHA. The reductase domain contains NADPH, flavin mononucleotide, flavin adenine dinucleotide and calmodulin-binding molecules, and functions to transfer electrons from NADPH to the oxygenase domain, which contains the binding sites for iron protoporphyrin IX (heme), heme, and substrate (L-arginine and NHA). Calmodulin controls communication between the two domains in that its binding triggers flavin-to-heme electron transfer in eNOS [19]. The combination of substrate and calmodulin binding to eNOS co-ordinates enzyme activity [20]. Heme iron reduction is thought to lead to oxygen activation of the enzyme and synthesis of NO in a stepwise reaction that requires 1.5 equivalents of NADPH per mole of NO formed (Fig. 1). More detailed reviews of the mechanisms of NOS catalysis are available from the literature [5,14].

Fig. 1. Catalytic cycle used by all NOS isoforms. The enzyme catalyses the oxidation of L-arginine to NHA. NADPH is required both before and after formation of the intermediate N⁵-hydroxy-L-arginine, so that 1.5 mol of NADPH being oxidized per mole of NO formed.

Weissman, 2012-12-06 A decade ago for most scientists investigating various issues in life sciences the word NO was used in a negative context It is astounding to observe how recently researchers are addressing the issue of NO namely nitric oxide in over fifty publications weekly Science journal while naming nitric oxide Molecule of the Year December 1992 said it all NO news is good news For a long period of time NO was considered as a pollutant and every ecology minded person tried to eliminate it It was the discovery of NO involvement in the process of host killing by macrophages and several years later the finding that EDRF is none else but NO that promoted this field Nitric oxide s major role in the control of blood pressure is merely one factor of an extensive list of effects and functions attributed to it NO is implicated in long term potentiation LTP a principal process involved in memory consolidation and it is considered as the main biochemical substance responsible for penile erection It should be noted that additional roles for NO are discovered continuously as many laboratories join the quest for the mystery of this small molecule The observation that NO is involved in various biological processes is not unique as other second messengers i e cyclic AMP participate in a diverse set of functions **The Biology of Nitric Oxide** S.
